In this comprehensive review, we will delve into typical organic chemistry final exam questions, accompanied by detailed answers, to help students refine their understanding and approach to exam preparation.

Understanding the Structure and Reactivity of Organic Molecules

1. Structural Identification and Nomenclature

Question:

Given the molecular formula C_7H_{16} , draw all possible structural isomers and name them according to IUPAC nomenclature.

Answer:

C_7H_{16} is an alkane with several structural isomers. The key is to systematically enumerate all possible arrangements of the carbon skeletons:

- Straight-chain isomers:
 - heptane (n-heptane): $CH_3(CH_2)_5CH_3$
- 2-methylhexane
- 3-methylhexane
- 2,2-dimethylpentane
- 2,3-dimethylpentane
- 2,4-dimethylpentane
- 3,3-dimethylpentane
- 3,4-dimethylpentane
- 3-ethylpentane
- 2,2,3-trimethylbutane

- Branched isomers:

These are derived from substituting methyl groups at various positions on the main chain, ensuring all unique structures are accounted for without duplicates.

Key Points:

- Use IUPAC rules for naming: identify the longest carbon chain, assign the lowest possible numbers to substituents, and list substituents alphabetically.
- For complex isomers, systematic drawing aids in avoiding duplicates.

2. Recognizing Functional Groups and Predicting Reactivity

Question:

Identify the functional groups present in the molecule below and predict its reactivity profile:

Image description: A molecule containing a benzene ring fused with a carbonyl group (a ketone).

Answer:

- Functional Groups Identified:
 - Aromatic ring (benzene): Provides aromatic stability and undergoes electrophilic aromatic substitution.
 - Ketone group ($\text{C}=\text{O}$): The carbonyl carbon is electrophilic, making the molecule susceptible to nucleophilic attack.
- Reactivity Profile:
 - The aromatic ring can undergo substitution reactions such as nitration, sulfonation, halogenation, and Friedel-Crafts acylation or alkylation.
 - The ketone functional group is reactive towards nucleophiles, capable of forming addition products, and can be reduced to secondary alcohols.
 - The conjugation between the aromatic ring and carbonyl may influence reactivity, often stabilizing or activating certain positions for substitution.

Implication:

This molecule can participate in diverse reactions, especially electrophilic aromatic substitution and

nucleophilic addition or reduction, making it versatile in synthesis.

Mechanisms and Reaction Pathways

3. Nucleophilic Substitution Mechanisms (SN1 vs SN2)

Question:

Compare the SN1 and SN2 mechanisms using the following substrate: tert-butyl chloride and methyl chloride. Predict the predominant mechanism for each and explain why.

Answer:

- Methyl chloride (CH_3Cl):
- Mechanism: SN2
- Reason: Methyl halides are primary alkyl halides with minimal steric hindrance, favoring a one-step bimolecular nucleophilic substitution.

- Tert-butyl chloride ($(\text{CH}_3)_3\text{CCl}$):
- Mechanism: SN1
- Reason: Tertiary alkyl halides are sterically hindered, making SN2 difficult. Instead, they favor SN1 via carbocation formation, which is stabilized by alkyl groups through hyperconjugation and inductive effects.

Additional Points:

- SN1:
- Two steps: carbocation formation followed by nucleophile attack.
- Rate depends only on substrate concentration.
- Racemization occurs if the carbon is chiral.

- SN2:
- One concerted step where nucleophile attacks as leaving group departs.
- Rate depends on both substrate and nucleophile concentrations.
- Inversion of stereochemistry (Walden inversion).

4. Electrophilic Addition to Alkenes

Question:

Describe the mechanism of the addition of HBr to propene and predict the major product.

Answer:

- Mechanism Steps:

- Protonation of the alkene:

The π electrons of propene attack a proton from HBr, forming a carbocation.

- The proton adds to the carbon that leads to the most stable carbocation (Markovnikov's rule).
- In propene, protonation occurs at the terminal carbon, forming a secondary carbocation at the middle carbon.

- Nucleophilic attack:

The bromide ion (Br^-) attacks the carbocation, leading to the formation of the product.

- Major Product:
- 2-bromopropane ($\text{CH}_3\text{CHBrCH}_3$) following Markovnikov's rule, the bromine attaches to the more substituted carbon.

Spectroscopy and Structural Elucidation

5. Interpreting NMR Spectra

Question:

A compound with the molecular formula $\text{C}_4\text{H}_{10}\text{O}$ shows the following NMR signals:

- A singlet at δ 2.1 ppm integrating to 3H
- A triplet at δ 1.2 ppm integrating to 3H
- A multiplet at δ 2.4 ppm integrating to 2H

Assign the structure and explain your reasoning.

Answer:

- The singlet at δ 2.1 ppm (3H) suggests a methyl group attached to a carbonyl (acetyl methyl).
- The triplet at δ 1.2 ppm (3H) indicates a methyl group adjacent to a methylene (ethyl group).
- The multiplet at δ 2.4 ppm (2H) points to a methylene next to an electronegative atom or carbonyl.

Likely Structure:

- The data fit ethyl acetate ($\text{CH}_3\text{COOCH}_2\text{CH}_3$):
- The methyl attached to the carbonyl (acetyl group) appears around δ 2.1 ppm.
- The methylene group (OCH_2) resonates around δ 2.4 ppm.
- The terminal methyl group (CH_3) attached to the methylene appears as a triplet at δ 1.2 ppm.

Conclusion:

- The compound is ethyl acetate, consistent with the number of carbons, oxygen, and the NMR signals.

Question What are the key differences between SN1 and SN2 reactions in organic chemistry? SN1 reactions are unimolecular nucleophilic substitutions that proceed via a carbocation intermediate and are favored by tertiary substrates, polar protic solvents, and weak nucleophiles. SN2 reactions are bimolecular, proceed via a single concerted step, favored by primary substrates, strong nucleophiles, and polar aprotic solvents. SN1 reactions have a rate dependent only on the

substrate concentration, while SN2 reactions depend on both substrate and nucleophile concentrations. How do resonance structures influence the stability of organic molecules? Resonance structures delocalize electron density across multiple atoms, which stabilizes the molecule. The more resonance forms a molecule has, and the greater the contribution of structures with full octets and minimal charge separation, the more stable the molecule. Resonance stabilization lowers the overall energy, making the compound more thermodynamically favorable. What is the role of stereochemistry in organic reactions, specifically regarding chiral centers? Stereochemistry determines the 3D spatial arrangement of atoms in a molecule, which affects how it interacts with other molecules. Chiral centers create enantiomers?mirror-image isomers?that can have vastly different biological activities. Reactions that create or break chiral centers can influence the stereochemical outcome, impacting the properties and reactivity of organic compounds. Explain the concept of aromaticity and the criteria a compound must meet to be considered aromatic. Aromaticity refers to the enhanced stability of cyclic, planar molecules due to conjugated π -electron clouds following Hückel's rule. To be aromatic, a compound must be cyclic, planar, fully conjugated, and contain $(4n + 2)$ π -electrons, where n is an integer ($n=0,1,2,\dots$). Aromatic compounds display unusual stability and characteristic spectroscopic properties. Describe the mechanism of nucleophilic addition to aldehydes and ketones. The nucleophilic addition mechanism involves the attack of a nucleophile on the electrophilic carbon of the carbonyl group. First, the nucleophile attacks the carbon, forming a tetrahedral alkoxide intermediate. Then, depending on the conditions, this intermediate can be protonated to give an alcohol. Aldehydes are generally more reactive than ketones due to less steric hindrance and greater electrophilicity. What are common methods used to distinguish between different functional groups in an organic compound? Common methods include infrared (IR) spectroscopy to identify characteristic bond vibrations, nuclear magnetic resonance (NMR) spectroscopy to determine the molecular framework, mass spectrometry (MS) for molecular weight and fragmentation patterns, and chemical tests (e.g., Tollens' test for aldehydes). These techniques help identify and differentiate functional groups based on their unique chemical and physical properties. How does conjugation influence the UV-Vis absorption spectra of organic molecules? Conjugation extends the π -electron system across multiple bonds, lowering the energy gap between HOMO and LUMO orbitals. This results in absorption of longer wavelengths (red shift) in the UV-Vis spectrum. The more extensive the conjugation, the greater the wavelength of maximum absorption (λ_{max}), which can be used to analyze the degree of conjugation in a molecule.
