Computational Fluid Dynamics (CFD) software like ANSYS Fluent provides a powerful platform to model such flows accurately. This comprehensive tutorial aims to walk you through the entire process of setting up, solving, and analyzing 2D incompressible Poiseuille flow, ensuring you grasp both the theoretical and practical aspects.

Understanding 2D Incompressible Poiseuille Flow

Before diving into simulation steps, it's crucial to understand the physical phenomena and governing equations behind Poiseuille flow.

What is Poiseuille Flow?

Poiseuille flow describes laminar, steady, incompressible flow of a viscous fluid through a confined geometry, such as a pipe or channel. It is characterized by a parabolic velocity profile resulting from the balance between pressure forces and viscous stresses.

Governing Equations

The flow is governed by the Navier-Stokes equations for incompressible flow:

- **Continuity Equation:** $\nabla \cdot \mathbf{u} = 0$
- **Momentum Equation:** $\rho \left(\frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} \right) = -\nabla p + \nabla^2 \mathbf{u}$

where:

- ρ = fluid density
- μ = dynamic viscosity
- p = pressure
- $\mathbf{u}$ = velocity vector

In steady, laminar, 2D flow, the pressure gradient drives the flow, resulting in a velocity profile

described analytically by:

$$v(y) = (\Delta p / (2\eta L)) (H^2/4 - y^2)$$

where:

- Δp = pressure difference across the length L
- H = channel height
- y = transverse coordinate

This classic flow scenario—steady, laminar, pressure-driven flow between two parallel plates—serves as both a benchmark problem and a stepping stone toward mastering more complex fluid behaviors. In this tutorial, we will explore the physical principles, mathematical formulations, and practical steps to simulate and analyze 2D incompressible Poiseuille flow effectively.

Introduction to 2D Incompressible Poiseuille Flow

2D incompressible Poiseuille flow describes the laminar flow of a viscous, incompressible fluid confined between two parallel, stationary plates separated by a distance (h) . Driven by a constant pressure gradient, this flow is characterized by a smooth, parabolic velocity profile. It is a fundamental problem in fluid mechanics, often used to validate CFD codes, understand viscous effects, and analyze flow behaviors in microchannels, blood vessels, and industrial applications.

Why Study Poiseuille Flow?

- Benchmark testing: Its analytical solutions serve as benchmarks for CFD validation.
- Fundamental physics: Provides insights into viscous effects, boundary layers, and pressure-driven flows.
- Practical relevance: Analogous to flow in microfluidic devices, pipelines, and biological systems.

Physical and Mathematical Foundations

Assumptions and Simplifications

To analyze 2D incompressible Poiseuille flow, the following assumptions are typically made:

- Steady flow (no time dependence)
- Incompressible fluid (constant density)
- Newtonian fluid (linear viscous stress-strain relationship)
- Laminar flow regime
- No-slip boundary conditions at the walls
- Uniform pressure gradient along the flow direction

Governing Equations

Given these assumptions, the flow is governed by the Navier-Stokes equations, which reduce considerably in this context:

- Continuity Equation (Mass Conservation):

$$\nabla \cdot \mathbf{u} = 0$$

$$\nabla \cdot \mathbf{u} = 0$$

$$\nabla \cdot \mathbf{u} = 0$$

- Momentum Equation (for steady, laminar, incompressible flow):

$$\rho (\mathbf{u} \cdot \nabla) \mathbf{u} = -\nabla p + \mu \nabla^2 \mathbf{u}$$

$$\rho (\mathbf{u} \cdot \nabla) \mathbf{u} = -\nabla p + \mu \nabla^2 \mathbf{u}$$

$$\rho (\mathbf{u} \cdot \nabla) \mathbf{u} = -\nabla p + \mu \nabla^2 \mathbf{u}$$

Where:

- $\mathbf{u} = (u, v)$ is the velocity vector
- p is pressure
- ρ is fluid density

- (μ) is dynamic viscosity

In the case of 2D Poiseuille flow between parallel plates aligned in the x-direction, the flow simplifies significantly.

Analytical Solution

For a pressure gradient $(\frac{dp}{dx})$, the velocity profile $(u(y))$ across the channel height (h) is:

$$u(y) = \frac{1}{2\mu} \frac{dp}{dx} (y^2 - hy)$$

with boundary conditions:

$$u(0) = 0, \quad u(h) = 0$$

The maximum velocity occurs at the channel centerline $(y = h/2)$:

$$u_{\max} = -\frac{h^2}{8\mu} \frac{dp}{dx}$$

The volumetric flow rate per unit width (Q) :

$$Q = \int_0^h u(y) dy = -\frac{h^3}{12\mu} \frac{dp}{dx}$$
