Theoretical Frameworks and Mathematical Formalisms

Gurdeep Raj's work is characterized by rigorous mathematical modeling, often involving complex equations and computational algorithms.

Quantum Mechanical Formalism

At the heart of his theoretical contributions is the Schrödinger equation:

$$\hat{H} \Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_n) = E \Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_n)$$

]

where $\hat{H}$ is the Hamiltonian operator, Ψ the wavefunction, and E the energy. Solving this for many-electron systems involves approximations such as Kohn-Sham equations in DFT:

$$\left[-\frac{\hbar^2}{2m} \nabla^2 + V_{\text{eff}}(\mathbf{r}) \right] \phi_i(\mathbf{r}) = \epsilon_i \phi_i(\mathbf{r})$$

]

where (V_{eff}) encapsulates exchange-correlation effects. Raj's development of new exchange-correlation functionals has improved accuracy in predicting electronic properties.

Reaction Rate Equations and Energy Profiles

Reaction kinetics often involve the Arrhenius equation:

[

$$k = A e^{-\frac{E_a}{RT}}$$

]

with (k) as the rate constant, (A) the pre-exponential factor, (E_a) the activation energy, (R) the universal gas constant, and (T) temperature. Raj's work extends these models by incorporating quantum tunneling effects and non-adiabatic transitions, providing a more comprehensive description of reaction rates, especially at low temperatures.

Statistical and Thermodynamic Models

Using ensemble theory, the partition function (Q) is central:

[

$$Q = \sum_i e^{-\frac{E_i}{k_B T}}$$

]

which allows calculation of thermodynamic properties like entropy (S) , enthalpy (H) , and free energy (G) . Raj has contributed to refining these calculations for complex systems, including solvated ions and nanostructured materials.
