Marine propulsion systems convert fuel energy into thrust to move ships through water. The most common type is the main engine-driven propeller system, typically powered by large diesel engines. The process involves:

- Fuel combustion in the engine’s cylinders generates mechanical power.
- This power drives the ship’s propeller via a shaft connected to the engine.
- The propeller creates a thrust force, pushing the vessel forward.
- Auxiliary systems like gearboxes, shaft bearings, and control systems optimize efficiency and power transmission.

Modern ships may also employ gas turbines, electric propulsion (e.g., azipods), or hybrid systems, each with specific operational principles suited for different vessel types.

2. What are the main types of marine engines, and what are their differences?

Marine engines are broadly categorized into:

- Four-stroke engines: These engines complete a power cycle in four strokes of the piston (intake, compression, power, exhaust). They are common in smaller vessels or auxiliary power units because of their fuel efficiency and lower emissions.

Differences include:

Aspect	Two-Stroke Engines	Four-Stroke Engines
	-----	-----
Power Cycles	Single	Double
Efficiency	Generally higher	Slightly lower
Maintenance	More complex	Simpler
Applications	Large ships, main propulsion	Smaller vessels, auxiliary power
